Abstract:

Background: Atopic dermatitis, also known as atopic eczema, is a common chronic-relapsing, inflammatory, and itchy eczematous skin disease that affects both adults and children. Asthma, food allergies, and allergic rhinitis are all related to atopic dermatitis, and having atopy in the family considerably increases the likelihood of developing this disease. Our study aims to assess knowledge and awareness of Atopic Dermatitis among adults living in Saudi Arabia.

Methodology: This is an observational cross-sectional study that was conducted in Saudi Arabia during 2023-2024. The sample size was estimated by Raosoft with a confidence level of 95% and a margin of error of 5%. The minimum sample size was 385. The data was collected through a standardized clear questionnaire, and its analysis was done using SPSS version 25.

Results: Knowledge score showed that the largest proportion of individuals or entities falls within the moderate level category, accounting for 48.6%. Furthermore, the data indicates that 44.0% participants are classified as low level. Conversely, the high-level category represents 7.3% of the participants. Awareness score showed that the majority of the population falls into the low level, accounting for 81.5% of the total sample. On the other hand, the data also reveals that 16.0% of participants have an average level of awareness. Additionally, the data shows that only 2.5% of the participants have a good level of awareness. Relationship between eczema and quality of life score showed that the majority of individuals (51.6%) reported a low relationship between eczema and quality of life score. Additionally, 22.9% of individuals reported an average relationship between eczema and quality of life score, while 25.4% reported a good relationship between eczema and quality of life score.

Conclusion: In conclusion, the Saudi general population exhibited poor knowledge and awareness levels towards eczema. Addressing the knowledge and awareness level of atopic dermatitis among

Volume 06 Issue 1 2024 ISSN:1624-1940 DOI 10.6084/m9.figshare.26172862 http://magellanes.com/

adults living in Saudi Arabia is a critical step towards improving the health and well-being of those affected by this condition.

Keywords: Atopic dermatitis, atopic eczema, cross-sectional study, Saudi Arabia.

Introduction:

Atopic dermatitis (AD), commonly known as atopic eczema, is a prevalent chronic inflammatory skin disorder that affects people of all ages [1]. It is more common in children, although it may initially appear or continue into adulthood [2]. It is the most common chronic inflammatory skin disorder worldwide [3]. Eczema, dry skin, and itching are common symptoms of atopic dermatitis (AD) [4]. People with atopic dermatitis frequently experience a significant impact on their quality of life [5]. Because of its symptoms, including pruritus, and its frequent incidence in visible places, atopic dermatitis (AD) may have a severe impact on patients' lives by negatively impacting various aspects of quality of life (QoL) [6]. Children with atopic dermatitis may also undergo a massive burden, with significant consequences on QoL as well as bullying at school and impacts on daily activities, schoolwork, and personal relationships [7]. Atopic dermatitis has a complicated etiology that involves skin barrier dysfunction, skin dysbiosis, and a dysregulated immune system [8]. Atopic dermatitis is related to other atopic disorders such as asthma, food allergies, and allergic rhinitis, and a family history of atopy is associated with a greatly higher chance of having Atopic dermatitis [9]. Several environmental factors, including diesel pollution, humidity, and skin irritants, are also related [10]. Immunoglobulin E (IgE) levels are frequently high in atopic dermatitis patients [11]. The clinical diagnosis is based on the Hanifin and Rajka criteria [12]. Patient education has the potential to increase patients' knowledge about this disease and how to manage it [13]. One of the most common noninfectious skin illnesses in the world, atopic dermatitis (AD) affects up to 20% of children and 2-8% of adults [14]. In 60%–65% of instances, atopic dermatitis begins in the first few months of life, and in 85% of cases, it starts before the age of five [15]. Atopic dermatitis is the most prevalent skin disorder in children, affecting up to 20% of them [16]. A study has been published on parental awareness shows that there was adequate knowledge among Saudi parents, with the majority (73.9%) identified as having an acceptable level of awareness [17]. Another study shows that educational programs seem to be more beneficial than conventional treatment in the long-term management of atopic dermatitis and should be for both patients and their parents [18]. In 2020, research has been conducted about the urgent need for increased educational outreach to healthcare professionals, patients, and their families about the medical significance of these conditions and provided management options given the high disease burden in early childhood and the significant proportion that persists into adulthood [19]. We undertook the present research due to insufficient Saudi study had previously explored the level of knowledge and awareness among adults regarding Atopic Dermatitis. The research finding is expected to aid health professionals with data about subsequent action to improve the general public's knowledge and coordinate future Atopic Dermatitis promotional initiatives.

Objectives: The purpose of the study is to assess the knowledge and awareness level of Atopic Dermatitis among adults living in Saudi Arabia.

Volume 06 Issue 1 2024 ISSN:1624-1940 DOI 10.6084/m9.figshare.26172862 http://magellanes.com/

Materials and Methods:

Study design: This is an observational cross-sectional study that was conducted in Saudi Arabia during 2023-2024.

Study setting: Participants, recruitment, and sampling procedure: The study's population consisted of Saudi adults over the age of 18, participants were recruited during 2023-2024 from people receiving the questionnaire.

Inclusion and Exclusion criteria: This study will include all male and female adults living in Saudi Arabia, adults living outside Saudi Arabia and children was excluded from the study.

Sample Size: The sample size was estimated by Raosoft with a confidence level of 95% and a margin of error of 5%. The minimum sample size was 385.

Method for data collection and instrument (*Data collection Technique and tools*): An online questionnaire was prepared and distributed by the data collectors to collect data from random people in Saudi Arabia. The questionnaire will include questions regarding the participants' sociodemographic (age, gender, and educational level) as well as questions about knowledge and awareness level of Atopic Dermatitis. In our study we will used questionnaire was done by [16,17,20].

Scoring System:

Knowledge score

There were Eight questions in this part and the general people were asked about their knowledge level of Atopic dermatitis. Each question had three choices. A correct answer was given a 1 score, whereas a 0 score was given for a wrong answer. Maximum score = 8 points

The scores for knowledge varied from 0-8 points and were classified into three levels as follows:

- 1. High level: 7-8 scores
- 2. Moderate level: 5-6
- 3. Low level: 0-4

Awareness score

A total of 10 statements were used to assess the awareness of Atopic dermatitis. For each correct answer, a score of 1 was considered. A score of "0" was provided for incorrect responses. A "2" score for all of the above, A response "I don't know" was similarly considered wrong and received a score of "0", whereas "I know very little" was considered 1 score, A response "I know" 2 score, Maximum score = 16 points, The respondent's awareness was divided into three categories:

- 1. Low level (0-9)
- 2. Average level (10-11)
- 3. Good level (12-16)

Self-assessment score

A total of 2 questions, For each correct answer, a score of 1 was considered. A score of "0" was provided for incorrect responses. "2" score for all of the above. The total score was calculated.

ISSN:1624-1940
DOI 10.6084/m9.figshare.26172862
http://magellanes.com/

Maximum score = 7 points

- 1. Low level (0-3)
- 2. Average level (4-5)
- 3. Good level (6-10)

Relationship between eczema and quality of life score

There were 4 statements, for each correct answer, a score of 1 was considered. A score of "0" was provided for incorrect responses A response "I don't know" was similarly considered wrong and received a score of "0", a Maximum score = 4 points

Analyzes and entry method: A pre-tested questionnaire was used in data collection. The questionnaire included questions about sociodemographic factors and awareness. Data was coded, entered, and analyzed using the Statistical Package for the Social Sciences version 25.

Results:

Table (1) showed that age distribution reveals that the majority of respondents fall within the 21-30 age group, constituting 40.9% of the sample, followed by the 31-40 age group at 16.1%. The gender distribution indicates a higher representation of females, accounting for 70.4% of the total respondents. In terms of nationality, the majority are Saudi nationals, comprising 94.1% of the sample. Geographically, the data is divided into five regions: East, Middle, North, South, and West, with the East and Middle regions having the highest representation at 34.3% and 25.0% respectively. Regarding education level, individuals with a Bachelor's degree make up the largest proportion at 52.8%, followed by those with a high school education at 23.9%. Occupationally, the sample is diverse, with students representing 33.2% and employees at 30.9%. The data also reflects a range of income brackets, with over 15,000 Saudi Riyals being the most common category at 36.5%. Lastly, the marital status distribution shows that singles and married individuals are the two major segments, accounting for 49.3% and 43.8% respectively.

The first question in table (2) asked whether the respondents had heard of atopic dermatitis, and the results show that 86.1% of respondents answered "Yes," 9.3% answered "No," and 4.6% answered "Don't know." The second question inquired about the respondents' beliefs regarding the contagiousness of atopic dermatitis. The results reveal that 20.8% of respondents believed it to be contagious, while 63.8% did not, and 15.4% were unsure. The third question focused on whether the respondents believed that their children might develop atopic dermatitis if they themselves had the disease. The responses show that 52.5% of respondents expressed concern that their children could develop atopic dermatitis if they had the condition, while 25.1% did not believe this to be the case, and 22.4% were unsure.

Parameter	Yes	No	Don't
			know
Heard of atopic dermatitis (eczema)	917	99	49
	86.1%	9.3%	4.6%
Think atopic dermatitis (eczema) can be	222	679	164
contagious	20.8%	63.8%	15.4%
Think your children might develop atopic	559	267	239
dermatitis (eczema) if you have the disease?	52.5%	25.1%	22.4%

Table (3) showed that according to participants the majority of atopic dermatitis cases affect the skin (91.1%), followed by a much smaller percentage affecting muscles (2.3%), bones (2.5%), the heart (1.3%), and other body parts (2.8%). The causes of atopic dermatitis vary, with a notable percentage attributed to unknown reasons (27.4%), bacterial infections (10.7%), and fungal infections (11.2%). A significant proportion also indicated a lack of knowledge regarding the causes (32.9%). According to participants atopic dermatitis is more commonly observed in children (60.2%) compared to teenagers (10.9%) and the elderly (5.5%). A substantial number of respondents also expressed uncertainty about its prevalence among different age groups (18.8%). Children with atopic dermatitis may commonly suffer from allergic rhinitis (27.4%) and asthma (25.6%). A significant proportion of respondents (46.9%) indicated a lack of knowledge about the associated diseases. According to participants the most prevalent symptoms of atopic dermatitis include itch (71.3%), rash (77.5%), and redness (68.5%). A smaller percentage expressed uncertainty about the symptoms (7.6%). A considerable number of respondents indicated a lack of understanding regarding eczema (68.9%) and its treatment plan (57.7%). The majority recognized the importance of maintaining skin moisture by applying cream or lotion (58.4%) and avoiding aggravating factors such as scented soaps and hot weather (61.5%). A significant majority acknowledged the need to apply a thin layer of steroid cream only to the red, itchy areas (63.3%). A substantial number of respondents recognized the need to contact the primary care center if specific symptoms or concerns arise (55.8%). Factors such as genetics (62.1%), the environment (53.4%), and immunity (48.0%) were identified by participants to be involved in the pathogenesis of atopic dermatitis. Furthermore, family history of atopy (eczema) was recognized as a known risk factor (67.0%).

Which of the following is a known risk	Family history of atopy (eczema)	714	67.0
factor for atopic dermatitis (eczema)?	Early exposure to antibiotics	244	22.9
-	Timing of introduction of solid foods	164	15.4
-	Loss of function mutations in the	287	26.9
	FLG gene		
-	Abstain from allergenic foods	306	28.7
-	High birth rates	95	8.9
-	Type of delivery during childbirth	123	11.5

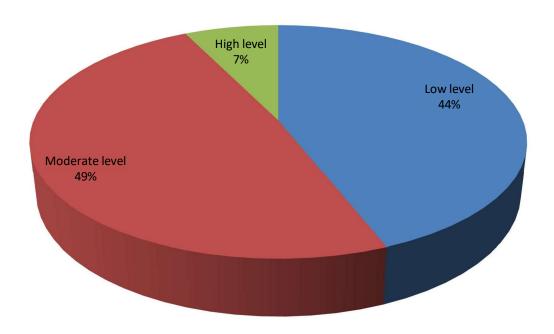

Table (4) showed that a significant portion of respondents, accounting for 34.6%, expressed the belief that atopic dermatitis could indeed affect school achievement and performance. On the other hand, 42.2% of respondents indicated that they did not think atopic dermatitis would have such an impact, while 23.3% were unsure. Moving on to the question of whether atopic dermatitis might pose challenges in making friends, the data indicates that a substantial 46.9% of respondents believe it could indeed lead to difficulties in forming social connections. In contrast, 32.5% of respondents disagreed with this notion, and 20.7% expressed uncertainty. Furthermore, the statistics pertaining to the potential impact of atopic dermatitis on diet behavior reveal that a majority of respondents, accounting for 54.1%, believe that the condition can influence dietary habits. Meanwhile, 25.2% of respondents disagreed with this perspective, and 20.8% were unsure. Lastly, the data related to the impact of atopic dermatitis on children's vaccination schedules presents a more balanced distribution of responses. A notable 38.2% of respondents expressed uncertainty about whether atopic dermatitis could affect vaccination schedules, while 32.7% believed it could, and 29.1% disagreed.

Table (4): Awareness of participants of atopic dermatitis (n=1065).

Parameter	Yes	No	Don't
			know
Do you think atopic dermatitis (eczema) will affect	368	449	248
school achievement and performance?	34.6%	42.2%	23.3%

children's vaccination schedule?	32.7%	29.1%	38.2%

According to the data in figure (1) showing knowledge score, the largest proportion of individuals or entities falls within the moderate level category, accounting for 48.6%. Furthermore, the data indicates that 44.0% participants are classified as low level. Conversely, the high level category represents 7.3% of the participants.

Figure 1 Knowledge score level of Atopic Dermatitis among adults living in Saudi Arabia

The data in figure (2) showed that the majority of the population falls into the low level awareness category, accounting for 81.5% of the total sample. On the other hand, the data also reveals that 16.0% of participants have an average level of awareness. Additionally, the data shows that only 2.5% of the participants have a good level of awareness.

Figure 2 Awareness score level of Atopic Dermatitis among adults living in Saudi Arabia

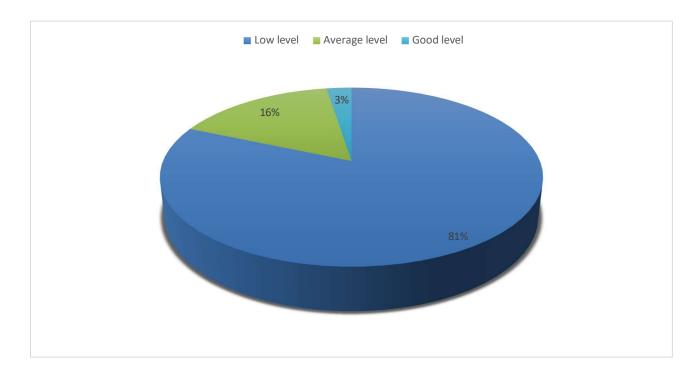

Figure (3) showed that the majority of individuals (51.6%) reported a low relationship between eczema and quality of life score. Additionally, 22.9% of individuals reported an average relationship between eczema and quality of life score, while 25.4% reported a good relationship between eczema and quality of life score.

Table (5) showed that age distribution among the 1065 participants, the majority fall within the 21-30 age group (40.9%), followed by the 18-20 age group (17.1%), and the 31-40 age group (16.1%). The percentages indicate the distribution of knowledge scores was higher among 21-30 age group, with a significant p-value of 0.001. Moving on to marital status, the data reveals that a substantial proportion of participants are single (49.3%) or married (43.8%), with relatively smaller percentages for divorced (5.0%) and widowed (2.0%) individuals. The p-value of 0.001 indicates a significant relationship between marital status and knowledge score. For single participants seemed to exhibit higher knowledge scores. In terms of gender, the majority of participants are female (70.4%) compared to male participants (29.6%). The p-value of 0.001 suggests a significant association between gender and knowledge score. For females exhibited higher knowledge scores. Regarding nationality, the vast majority of participants are Saudi (94.1%), with a smaller percentage being non-Saudi (5.9%). The p-value of 0.618 indicates a non-significant association. The location data illustrates that the highest percentage of participants are from the East region (34.3%), followed by the Middle (25.0%) and West (18.1%) regions. The p-values (0.005) suggest a significant association between location and knowledge score. East residents exhibited higher knowledge scores. Looking at education level, the majority of participants hold a Bachelor's degree (52.8%), followed by high school (23.9%) and graduate studies (6.5%). The p-value of 0.038 indicates a significant association between education level and knowledge score. For participants with bachelor's degree exhibited higher knowledge scores. In terms of occupation, the largest percentage of participants was students (33.2%) and employees (30.9%), followed by unemployed individuals (20.0%). The p-value of 0.001 highlights a statistically significant association between occupation and knowledge score. For students exhibited higher knowledge scores. Finally, the data on income shows that the majority of participants fall within the over 15,000 Saudi Riyals income bracket (36.5%),

ISSN:1624-1940 DOI 10.6084/m9.figshare.26172862 http://magellanes.com/

followed by the 5,000 - 10,000 (27.5%) and 11,000 - 15,000 (22.7%) brackets. The p-value is 0.004, as participants with income over 15000 Saudi Riyals exhibited higher knowledge scores.

Table (6) showed that in terms of age, the study found that the majority of participants fell within the age range of 21-30 years old, with 40.9% of the total participants falling within this age group. Regarding marital status, the study found that the majority of participants were either single or married, with 49.3% and 43.8% of the total participants falling within these categories, respectively. In terms of gender, the study found that the majority of participants were female, with 70.4% of the total participants falling within this category. In terms of nationality, the study found that the majority of participants were Saudi, with 94.1% of the total participants falling within this category. Regarding location, the study found that the majority of participants were from the eastern region of Saudi Arabia, with 34.3% of the total participants falling within this category. In terms of education level, the study found that the majority of participants had a Bachelor's degree, with 52.8% of the total participants falling within this category. Regarding occupation, the study found that the majority of participants were either employees or students, with 30.9% and 33.2% of the total participants falling within these categories, respectively. Finally, in terms of income, the study found that the majority of participants had an income of over 15,000 Saudi Riyals, with 36.5% of the total participants falling within this category. All sociodemographic characteristics had no significant association with awareness score.

Table (6): Association between sociodemographic characteristics and awareness score (n=1065).

Table (7) shows that there is no significant relationship between age and quality of life scores, as indicated by the P value of 0.779. Across different age groups, the percentage of individuals with low quality of life scores remains relatively consistent, ranging from 7.7% to 17.1%. Similarly, marital status does not appear to have a significant association with quality of life scores, with a P value of 0.105. The percentages of individuals with low quality of life scores are fairly consistent across the categories of single, married, divorced, and widowed individuals, ranging from 2.0% to 5.0%. In terms of gender, the data indicates that there is no significant relationship between gender and quality of life scores, with a P value of 0.543. The percentages of individuals with low quality of life scores are consistent across male and female respondents, ranging from 14.7% to 36.9%. The nationality of the respondents also does not seem to have a significant association with quality of life scores, as indicated by a P value of 0.148. The percentages of individuals with low quality of life scores are relatively consistent between Saudi and non-Saudi nationals, ranging from 2.0% to 48.5%. Furthermore, the location of the respondents does not show a significant relationship with quality of life scores, with P values ranging from 0.186 to 0.828. The percentages of individuals with low quality of life scores are consistent across different regions, ranging from 4.6% to 18.8%. Education level also does not appear to have a significant association with quality of life scores, as indicated by a P value of 0.828. The percentages of individuals with low quality of life scores are relatively consistent across different education levels, ranging from 0.3% to 26.9%. Similarly, occupation does not show a significant relationship with quality of life scores, with a P value of 0.137. The percentages of individuals with low quality of life scores are consistent

across different occupations, ranging from 1.9% to 16.1%. Finally, the data suggests that income in Saudi Riyals does not have a significant association with quality of life scores, as indicated by P values ranging from 0.469 to 0.823. The percentages of individuals with low quality of life scores are relatively consistent across different income levels, ranging from 6.9% to 19.9%.

Discussion:

Atopic dermatitis, also known as eczema, is a common chronic skin condition that affects millions of people worldwide. It is characterized by red, itchy, and inflamed skin that can be both physically and emotionally distressing. In Saudi Arabia, the prevalence of atopic dermatitis among adults is not well-documented, and there is limited research on the knowledge and awareness level of this condition among the general population [1-3]. One of the key factors that contribute to the lack of knowledge and awareness about atopic dermatitis in Saudi Arabia is the stigma associated with skin conditions. Many people are reluctant to seek medical help or openly discuss their skin issues due to fear of judgment or discrimination. This can lead to a lack of understanding about the condition and its management, which in turn can result in inadequate treatment and poor quality of life for those affected by atopic dermatitis [8].

Furthermore, there is a shortage of educational resources and public health campaigns focused on atopic dermatitis in Saudi Arabia. This lack of information can lead to misconceptions and myths about the condition, which can further hinder the ability of individuals to seek appropriate care and support [12].

Our study showed that knowledge the largest proportion of individuals or entities falls within the moderate level category, accounting for 48.6%. Furthermore, the data indicates that 44.0% participants are classified as low level. Conversely, the high level category represents 7.3% of the participants, indicating inadequate knowledge score. Inconsistent with a study that evaluated the level of awareness among Saudi parents regarding atopic dermatitis. It was found that 73.9% of the parents demonstrated a high level of awareness [17], which is consistent with previously reported findings from Serbia, Belgrade, by Reljić et al. In their study, the average score of parental knowledge regarding children with atopic dermatitis was reported to be 9.5 ± 1.9 out of 12 [21].

In our study awareness score was inadequate as 81.5% had low level of awareness. Also we found that more than half of the participants (51.6%) had low relationship between eczema and quality of life score. In order to substantiate our results, Alkatheri conducted a study on prevalent dermatological conditions, which revealed that around 94% of primary healthcare practitioners exhibited inadequate knowledge, as indicated by their scores falling below 60%. Previous investigations conducted in Bulgaria [23] and Mediterranean islands likewise found low knowledge scores [24].

In our study there was no significant association found between sociodemographic characteristics and awareness score or relationship between eczema and quality of life score. There were significant association found between sociodemographic characteristics and knowledge score, as age (p-value= 0.001), marital status (p-value= 0.001), gender (p-value= 0.001), location (p-value= 0.005), education

Volume 06 Issue 1 2024 ISSN:1624-1940 DOI 10.6084/m9.figshare.26172862 http://magellanes.com/

level (p-value= 0.038), occupation (p-value= 0.001), and income (p-value= 0.004). Similarly, there was a notable distinction in awareness levels based on age (p = 0.000). The results indicated that individuals between the ages of 25-39 had a higher level of awareness compared to other age groups [17]. This finding contradicts the previous study conducted by Reljić et al., which found that older parents (p = 0.040) were more likely to have a greater understanding of atopic dermatitis [21]. A strong correlation was found between marital status and level of awareness (p = 0.000). Married parents exhibited the highest level of awareness [17], which aligns with the findings reported by Reljić et al [21]. It was observed that married or partnered parents (p = 0.004), as well as those who had experienced atopic dermatitis themselves, were more likely to possess greater knowledge about atopic dermatitis [17].

It is crucial to address the knowledge and awareness gap surrounding atopic dermatitis in Saudi Arabia in order to improve the quality of life for those affected by the condition. This can be achieved through targeted educational initiatives aimed at increasing public awareness, dispelling myths, and reducing stigma. Healthcare providers also play a crucial role in educating their patients about atopic dermatitis and providing them with the necessary support and resources to manage their condition effectively [18]. In addition, more research is needed to better understand the prevalence and impact of atopic dermatitis in Saudi Arabia. This will help to inform public health strategies and policies aimed at improving the management and care of individuals with atopic dermatitis.

The study provides valuable insights into the understanding and awareness of atopic dermatitis among adults in Saudi Arabia. However, it is important to acknowledge the limitations of the study in order to provide a comprehensive understanding of its findings. One limitation of the study is the potential for selection bias, as the sample population may not be representative of the entire adult population in Saudi Arabia. Additionally, the study may be limited by the use of self-reported data, which can introduce response bias and inaccuracies. Furthermore, the study may not account for cultural or regional differences within Saudi Arabia, which could impact the generalizability of the findings. Despite these limitations, the study provides valuable insights into the knowledge and awareness of atopic dermatitis among adults in Saudi Arabia, and serves as a foundation for future research in this area.

The findings of this study can help healthcare professionals and policymakers in Saudi Arabia to develop targeted educational programs and interventions to improve the understanding and management of atopic dermatitis in the adult population. By increasing awareness and knowledge about this chronic skin condition, it is possible to reduce the burden of atopic dermatitis and improve the quality of life for affected individuals. Additionally, this study can also serve as a foundation for future research on atopic dermatitis in Saudi Arabia, leading to advancements in treatment and care for those living with this condition. Overall, the implications of this study have the potential to make a positive impact on the healthcare system and the lives of adults with atopic dermatitis in Saudi Arabia.

Conclusion:

In conclusion, the Saudi general population exhibited poor knowledge and awareness levels towards eczema. Addressing the knowledge and awareness level of atopic dermatitis among adults living in Saudi Arabia is a critical step towards improving the health and well-being of those affected by this condition. Also, by increasing awareness, reducing stigma, and providing access to appropriate care and

support, we can make a positive impact on the lives of individuals living with atopic dermatitis in Saudi Arabia.

Acknowledgement:

We thank the participants who all contributed samples to the study.

Ethical approval

Ethical approval was obtained from the research ethics committee of the Ministry of health with Application number[A01843]. An informed consent was obtained from each participant after explaining the study in full and clarifying that participation is voluntary. Data collected were securely saved and used for research purposes only.

Funding

The study did not receive any external funding.

Conflict of interests

The authors declare that there are no conflicts of interest.

Informed consent:

Written informed consent was obtained from all individual participants included in the study.

Data and materials availability

All data associated with this study are present in the paper
